

What is the Nernst Equation?

Worksheet

$E = E^\circ - \frac{RT}{nF} \ln(Q)$, where E is actual potential, E° is standard potential, R is gas constant, T is temperature (K), n is electrons transferred, F is Faraday constant, and Q is reaction quotient.

$$E = E^\circ - \frac{RT}{nF} \ln(Q)$$

Questions

1. Nernst equation: $E = E^\circ - \frac{RT}{nF} \ln(Q)$. At $Q=1$, E equals:

- A) 0 V
- B) E°
- C) $E^\circ + \frac{RT}{nF}$
- D) cannot determine

2. As Q increases (reaction progresses), E :

- A) increases
- B) decreases to zero
- C) stays constant
- D) becomes negative

3. What is $\ln(Q)$ at equilibrium?

- A) 0
- B) 1
- C) $\ln(K)$
- D) infinity

4. Doubling temperature T at $Q=1$ does what to E ?

- A) increases by 2
- B) decreases
- C) stays same as E°
- D) halves

5. Zn-Cu cell at 25°C, $n=2$, $E^\circ=1.10$ V. If $Q=4$, what is E ?

6. At equilibrium ($Q=K$), what is E ?

7. Temperature doubles from 298 K to 596 K, $Q=1$, $n=1$, $E^\circ=0.5$ V. New E ?

8. Define: What does the Nernst equation calculate?

9. Define: At what condition is $E = E^\circ$?

10. Define: What happens to E as Q increases toward K ?

Answer Key

1. B) $E - \ln(1)=0$, so $E = E^0 = E$.
2. B) decreases to zero - $\ln(Q)$ increases, so E (positive number) = decreases.
3. C) $\ln(K)$ - At equilibrium $Q=K$, so $\ln(Q)=\ln(K)$.
4. C) stays same as E - At $Q=1$, $\ln(Q)=0$, so $E = E$ regardless of T .
5. $E = 1.10 (8.314298)/(296485)\ln(4)$ $E = 1.10 \cdot 0.025691 \cdot 386$ $E = 1.10 \cdot 0.0356 = 1.064$ V
6. When $Q=K$: $\ln(Q) = \ln(K)$ $E = E - (RT/nF)\ln(K) = 0$ V (The cell voltage is zero at equilibrium.)
7. $E = 0.5 (8.314596)/(196485)\ln(1)$ $\ln(1)=0$ so $E = 0.5$ V (At $Q=1$, $E=E$ regardless of T .)
8. The actual cell potential E when concentrations (Q) differ from standard conditions.
9. When all concentrations are 1 M ($Q = 1$), so $\ln(Q) = 0$.
10. E decreases toward zero (less voltage available as the reaction approaches equilibrium).
